Selective detection of clinically relevant mutations in rare fragile X syndrome cases by fluorescence in situ hybridization and locus-specific PCRs. Fragile X syndrome (FXS) is a frequent cause of intellectual disability with clinical heterogeneity due to the occurrence of somatic mutations in the FMR1 gene. Although both mental retardation and the fragile X phenotype are triggered by the loss of the protein FMRP, the molecular mechanisms are not completely understood. We have examined 11 female FXS patients by means of fluorescence in situ hybridization (FISH) and locus-specific PCR to determine the presence and nature of mutations in the FMR1 gene. In all cases, FISH with the MLPA05 system was able to detect the 5' and 3' portion of FMR1, where the breakpoints occur. All 6 patients analyzed by locus-specific PCR detected a pre-mutation, consisting of at

least two trinucleotide repeats on both sides of the polymorphic trinucleotide CCG. Five patients were positive for a full mutation, in which a stretch of 51 CGG trinucleotide repeats was present in the 5' region of the FMR1 gene. In one patient, deletion of the 3' portion of FMR1 was detected. One patient, who was negative for pre-mutations, had a full mutation, consisting of a > 200 CGG repeat region. Our data suggest that FISH analysis of lymphocytes is a sensitive and reliable method for identifying the genomic mutation in FXS patients. This method allows a rapid diagnosis to be established, which is important for patient management and counselling of FXS.
